Auroral Electrojet Indices (AE)

for July - December 1979

by

T. Kamei and H. Maeda

1. Introduction

The Auroral Electrojet index (AE) was originally introduced by Davis and Sugiura in 1966 as a measure of global electrojet activity in the auroral zone, and it is now widely used for studying geomagnetism, aeronomy and solar-terrestrial physics. The index was first derived at the Geophysical Institute of the University of Alaska, and hourly values were published for the years 1957 to 1964. The production of 2.5-min values was then tried at the Goddard Space Flight Center of NASA, and the results from September 1964 to June 1968 were published.

After that, the index was regularly published at the World Data Center A in Boulder, Colorado, and the Center published 2.5-min values for the years 1966 to 1974 and 1.0-min values for 1975 and a half of 1976. We have published AE values for the year 1978 and 1979 as part of the data books (No.3 and No.4 for 1978 and No.5 for the first half of 1979). Please see data books No.3 or No.4 for the estimation of errors of our AE data.

2. Derivation and Representation

The AE index is derived from the horizontal component of geomagnetic variations observed at some (10-13) observatories along the auroral zone in the northern hemisphere. To normalize the data from each station, a base value of each station for each month is first calculated by averaging all the data of the station on the five international quiet days, and this base value is subtracted from every-day data of the station in that month. Then the largest and smallest values are selected from all the stations. The largest value is called the AU index and the smallest value is called the AL index. These names came from the upper and lower envelopes of the overlapped figure of the data from these stations. The difference between the AU and AL indices gives the AE index, and the mean value of the AU and AL indices gives the AO index. The term "AE indices" is usually used to describe those four indices (AU, AL, AE and AO) in all.

The AU and AL indices are understood to express the strongest current density of the eastward and westward auroral electrojet, respectively.

The AE index is understood to represent the overall activity of the electrojets, and the AO index is regarded as a measure of the equivalent zonal current.

In this report we shall present every-day diagrams and hourly values of the AE indices and "Contributing stations plot" of the AE indices which may give more information about the indices. That is, we named the stations which give the AU and AL indices "the contributing stations of the AU and the AL index, respectively, and a pair of these AU and AL contributing stations "the contributing stations of AE indices". The plot gives these AE contributing stations on a plane whose coordinates are UT in abscissa and LT in ordinate at the stations. For users who want to check the AE indices precisely, this plot gives an information about data availability of each station. Thus the plot will give us an idea which data are to be checked. For these users, we would like to suggest to check our way of derivation of the AE indices and our estimation of errors.

3. Selection of Observatories

To obtain good AE indices, we must use as many observatories as possible, but we meet two big difficulties: One is that the distribution of active observatories are not uniform over the auroral zone, and the other is that the digitization of analogue data (magnetograms) is a heavy job.

We selected 12 observatories listed in Table 1. Of these, only 5 stations are taking digital data directly (called digital stations). Our selection is almost the same as that of the WDC-A. (see Fig. 1)

Three of the stations (Fortchurchill, Great Whale River, and Yellowknife) are the digital stations which give data in the X, Y, Z coordinate system. To make these data more compatible to other stations, we converted the X and Y components to H component by $H=(X^2+Y^2)^{1/2}$, and we treated the resulted H component to be missing for the period either X or Y is missing. For other two digital stations (Barrow and College), we used the original digital H-component data.

4. Digitizing Machine

Our digitizing machine is made of a semi-automatic sonic digitizer, a large size microfilm reader and a mini computer system.

The sonic digitizer has a pointing pen and two microphone arrays. The pen emits a small sonic pulse from a small electric spark at the top of it. The position of the pen is detected by time lags between the spark and signals received by the microphone arrays. One of the microphone arrays is

Table 1. List of AE(12) stations.

Observatory	Abbreviations		Geographic		Geomagnetic	
	ILAGA	WDC-A	Lat. ($^{\circ}$ N)	Long. ($^{\circ}$ E)	Lat. ($^{\circ}$ N)	Long. ($^{\circ}$ E)
Abisko	ABK	AI	68.36	18.82	66.04	115.08
Dixon Island	DIK	DI	73.55	80.57	63.02	161.57
Cape Chelyuskin	CCS	CC	77.72	104.28	66.26	176.46
Tixie Bay	TIK	TI	71.58	129.00	60.44	191.41
Cape Wellen	CWE	UE	66.17	190.17	61.79	237.10
Barrow	BRW	BW	71.30	203.25	68.54	241.15

Yellowknife	YKC	YEK	62.40	245.60	69.00	292.80
Fort Churchill	FCC	FC	58.80	265.90	68.70	322.77
Great Whale River	GWC	GWR	55.27	282.22	66.58	347.36
Narssarssuaq	NAQ	NAS	61.20	314.16	71.21	36.79
Leirvogur	LRV	LR	64.18	338.30	70.22	71.04

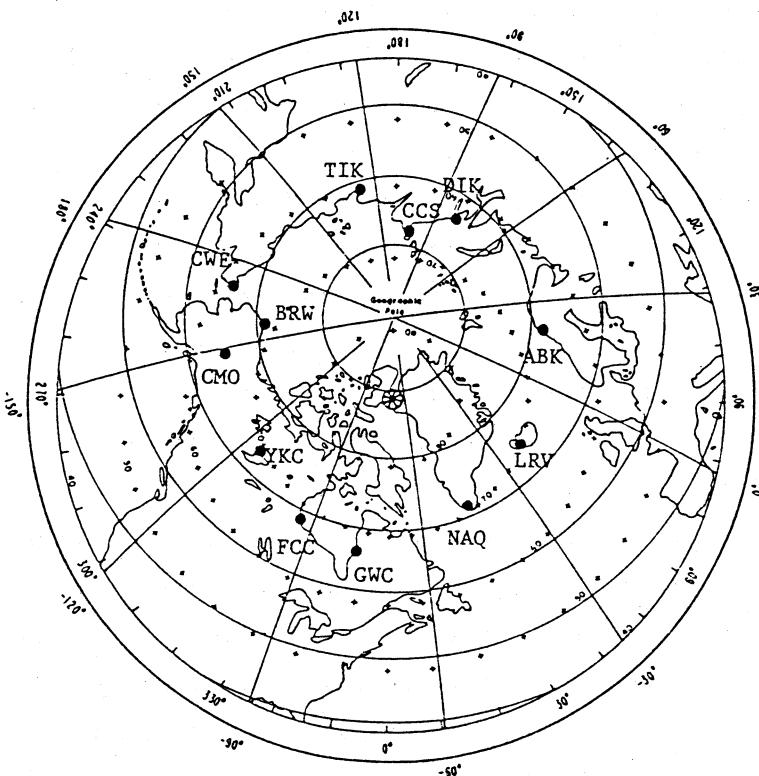

Fig. 1. Distribution of AE(12) stations.

Geographic latitude is indicated by the concentric circles of solid lines. Geomagnetic latitude is indicated by the numbered concentric circles formed by '+' signs. Geographic longitude is given by the outer circle of numerical values with meridians shown as solid lines every 30° . Geomagnetic longitude is given by the inner circle of numbers and the border of hash-marks at 10° intervals.

placed on the upper side of a microfilm reader and detects Y position of the pen, and another array is placed on the left side of the reader and detects X position of the pen.

The operator traces the projected figure (magnetogram) on the screen of the microfilm reader. The effective size of the screen is about 60 cm in width and about 40 cm in height. This screen is divided into 4000 x 3000 digital points. The emitting speed of the sparks can be controlled either by the computer or by the operator. Although the emitting speed can be as fast as 100 points per second, available speed is limited to 20 points per second, because of the speed of the CPU of computer and the recording media.

5. Digitization of Analogue Data

The magnetogram on 35 mm microfilm is projected directly on our microfilm reader. The projected figure is almost the same size as the original magnetogram whose size is about 2 cm/hour or 48 cm/day.

Usually, the magnetograms are digitized day by day. When the time marks on the magnetogram are not spaced uniformly or base lines are not straight enough, one magnetogram is divided into several uniform parts and then digitized. We used the ordinary magnetogram for all days. When the H trace crosses other traces, we tried to identify the H trace by referring the insensitive or storm magnetogram. When we trace the H component on magnetograms, we also feed three basic points to define the time and the absolute value of the digitized data, and feed other necessary information like the station identification and observation date.

In digitizing analog data, we could have trouble from the digitizer noise. To be free from such a noise, we digitized as many points as possible to get one value. In determining the three basic points we digitized each point more than 20 times, and we picked the point only when these consecutive 20 readings are all within a limited area. The traced digital data are logically checked by a quality control program to reject spikes caused by the noise. After cleaning by the quality program, the data are averaged to get the final one minute value. Usually, one-min value is determined from an average of 3 or 4 digital readings. We checked all the digitized data visually by the plot on a monitoring graphic display at the reading stage and by the finer common scale plot made by a X-Y plotter after processed by the quality control program.

6. The Overlapped Plot and the Plot of the Contributing Stations of the AE Indices.

Fig. 2a shows an example of the overlapped plot of the H traces from the AE stations on April 10, 1978. The upper envelope gives the AU index and the lower envelope gives the AL index. Figs. 2b and 2c show example plots of the contributing stations for the same day as in Fig. 2a, in the geomagnetic (2b) and geographic (2c) local times, where the upper and lower plumes on a diagonal line for each station show the contribution to the AU and AL indices of this station. In Fig. 2b, for example, the data of Dixon Island (DIK) give the AU index from 0000 to 0240 UT and again from 1330 to 1530 UT, and the AL index from 0640 to 0830 UT. It is seen that from 1100 to 1200 UT Leirvogur (LRV) offers no data. Since this is a key station for the AL index at that time, the exact AL values at that time have been lost.

We think some explanation are necessary for our trial plots of the contributing stations. On the plots hereafter, the ordinate is the geomagnetic local time (MLT). The MLT is defined by the difference of the geomagnetic longitude of the station and the geomagnetic longitude of the Sun, and it is a function of the geomagnetic longitude of the station, season, and universal time. Figs. 3a, 3b, 3c show the difference between the GLT and the MLT of the stations used to derive AE indices for winter, summer and equinox, respectively. In these figures the GLT is shown by the straight line which runs diagonally, and the MLT is shown by the T (or inverted T) shaped mark. The length of the vertical line between the T (or inverted T) shaped mark and the diagonal line is the difference between GLT and MLT.

Note that for some stations the difference between GLT and MLT is as much as 2 hours. The geomagnetic longitude of Cape Wellen (CWE) and Barrow (BRW) are very close, and so it is difficult to separate these two stations on the contributing stations plot. Sometimes, Cape Wellen gives AU and Barrow gives AL, and vice versa. This is thought to be an effect of local current system between the high latitude station and the low latitude station.

When we assume that the observed geomagnetic H component is a result of a simple combination of some simple current systems, this plot of the contributing stations can be regarded as an index of dominant current system at a certain time, though the current system in the auroral zone

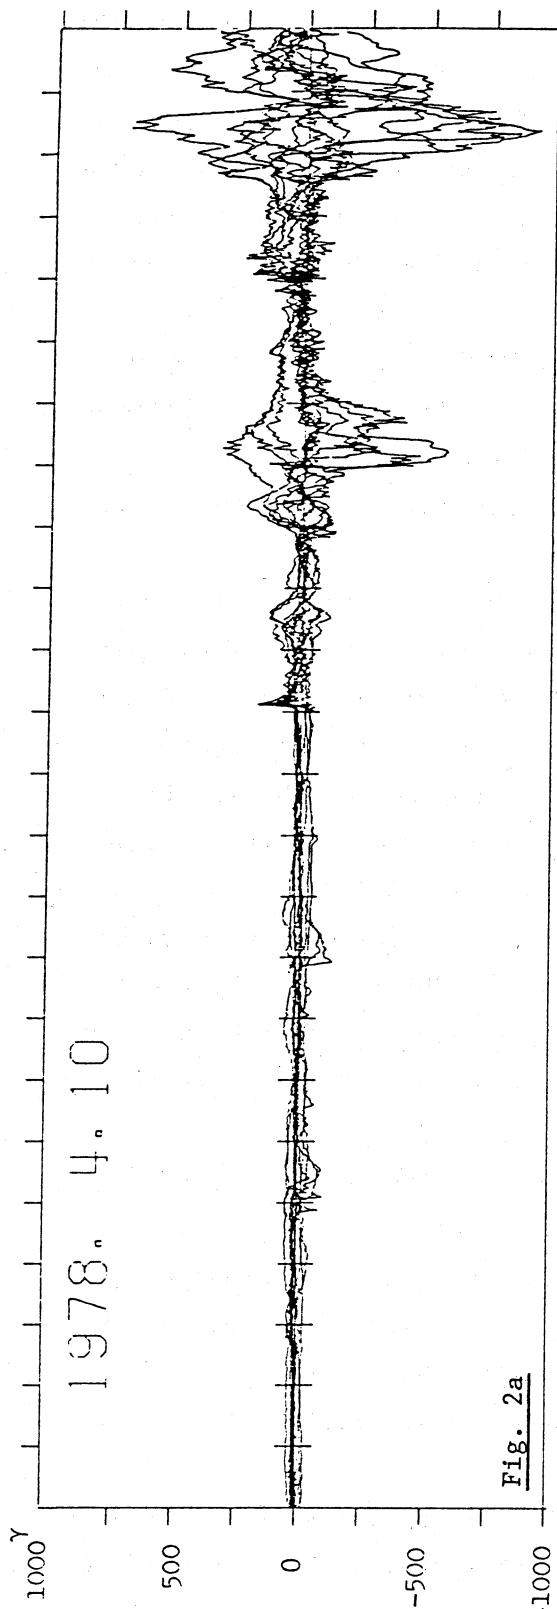

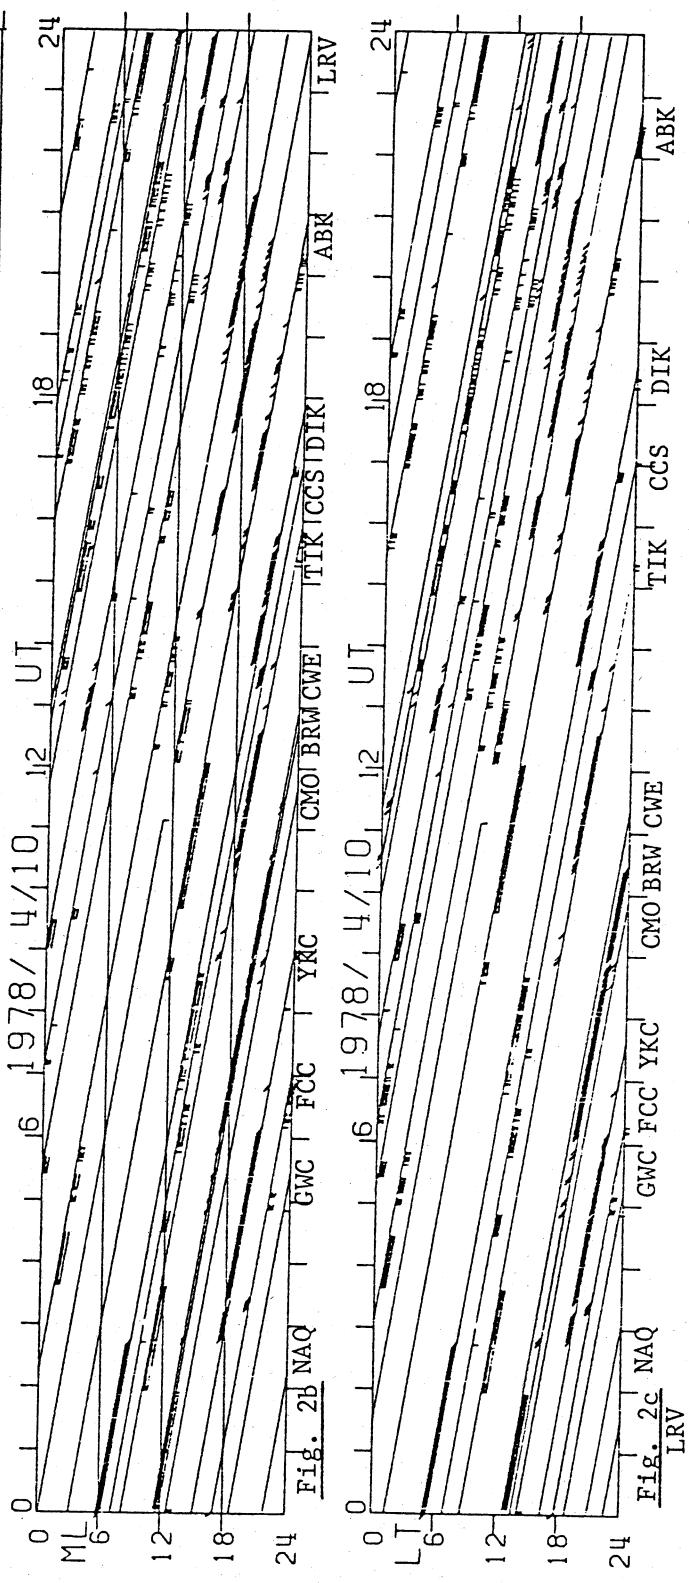

Fig. 2a

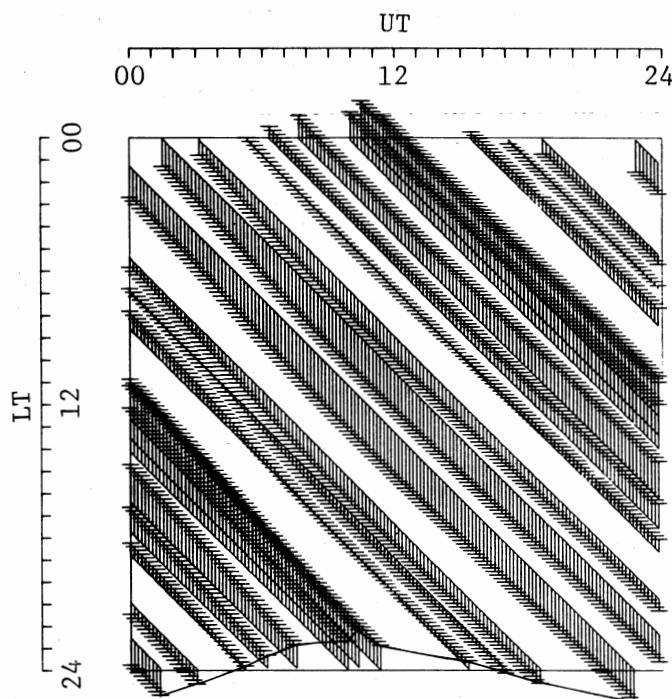

Fig. 3a Difference between GLT and MLT in winter.

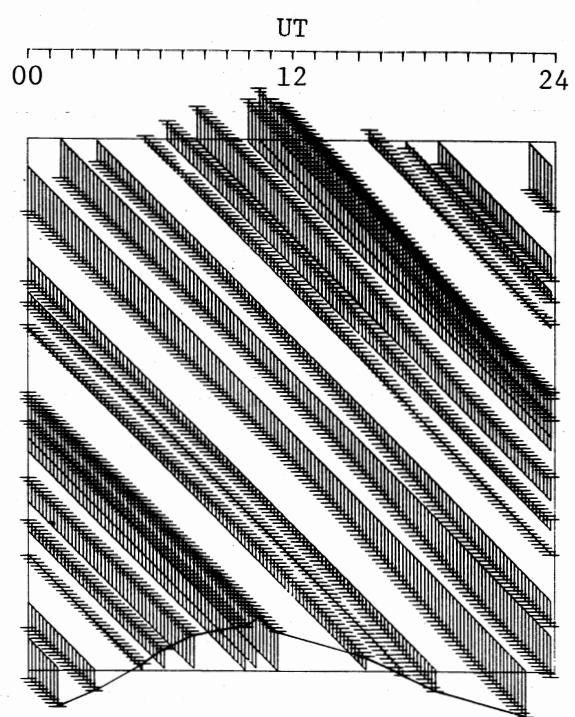

Fig. 3b Difference between GLT and MLT in summer.

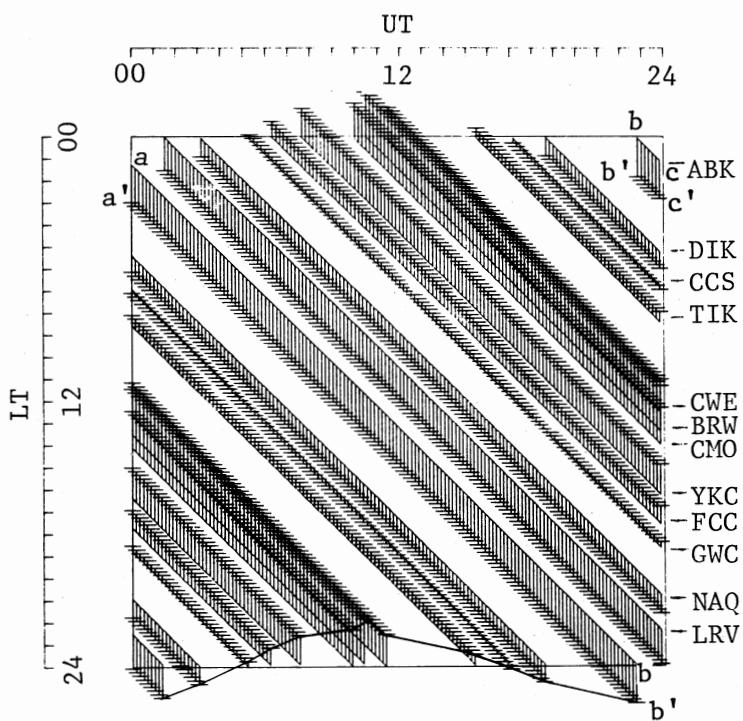

Fig. 3c Difference between GLT and MLT in equinox.

Fig. 3a, 3b and 3c show the difference between the geographic local time (GLT) and the geomagnetic local time (MLT) for winter, summer and equinox, where a-b-c (full line on the top or bottom of the vertical lines) shows the relation between UT and GLT, and a'-b'-c' (crossing of the vertical and horizontal lines) shows the relation between UT and MLT for each of the AE(12) stations.

is not very simple, and users must be very careful to check if local current systems may give a false impression of different current systems.

Although we have such limitation of the plot of the contributing stations, and we need more precise analyses, we can point out some characteristics from the plot, most of them confirm our previous knowledge.

(1) In quiet periods, the geomagnetic local time of the contributing stations to the AL index (called here AL time, shortly) is around noon. This is seen best in equinox. This may come from the low latitude Sq current system or from the field-aligned current system connected to the cusp region, or from both of them.

(2) In disturbed periods, the AL time is between midnight and morning.

(3) In some transition periods between quiet and disturbed states, the AL time moves gradually from noon to morning. Then, very sharp and short period AL spikes are seen and the AL time goes pre-midnight. Afterward, the AL time comes back to early morning.

(4) The geomagnetic local time of the AU contributing station (called AU time) is confined in the evening in disturbed periods. But in quiet periods, the AU time is distributed widely and it can be seen at midnight or in the morning.

7. Results

Monthly quiet-time H reference values for July-December 1979 are listed in Table 2, where for four stations only deviations (H_0^+) from the H base line are given, because we did not find out any base values. Table 3 gives the hourly average of AE indices on every day from July to December 1979.

Daily graphs of 1.0-min AE indices (AU, AL, AE and AO) are shown in Fig. 4, and corresponding plots of the contributing stations are shown in Fig. 5. Finally, Fig. 6 shows the H-traces of magnetograms from AE(12) stations in every month from July to December 1979.

8. Acknowledgements

This volume has been accomplished by the data supply from the AE stations through the World Data Centers and the financial support from the Ministry of Education, Science and Culture of Japan. Acknowledgement is due to Ms. Yohko Yamamoto for her assistance in digitizing magnetograms.

Note: Another example of wrong index is seen in the following figure; where the AU index around 1530 and 1620 (indicated by arrows) is incorrect, because of a lack of data at a key station for this index.

Digitizing System at the WDC-C2 for Geomagnetism

Kyoto University

1. Introduction

This is a brief description of the digitizing system at our data center. This system is used to digitize the ordinary magnetograms to derive AE indices for 1978 and 1979. The system can be used for similar digitizing jobs, but some minor changes may be necessary for other purposes. This is a special system with minicomputer, but techniques used in this system are also useful to other systems.

Fig. 1 illustrates the hardware at our data center. In many applications, more simple hardware may be enough. So we list some check points to construct a new digitizing system. First, the size of the CPU depends upon if the system is used only for digitization or used also for data processing. For the former, a small CPU will be enough without many peripherals or high speed channels. Second, the most important point is, of course, the selection of digitizer. We used a sonic digitizer because this allows correction of the original data before digitization, and also this can digitize ones on microfilm directly. Most common digitizer does not allow digitization of ones on microfilms but those on paper prints. The digitizer must be suitable in size for the object figure, and must have enough resolution and stability. The digitizer may not be computer controlled, but the output from the digitizer must be connected to the computer through a high speed channel or through a high speed communication line.

The output of the CPU (or the digitizer itself) must be recorded on large external memories like magnetic tapes or disks. And, the recording speed must be fast enough to keep up with the input speed. It is recommended to install a high speed graphic display which allows a quick look check of the digitized data.

2. Characteristics of the analogue data

We must know the characteristics of the analogue data to make digitization with necessary accuracy. This system is designed to digitize what

we call normal-run magnetograms. Fig. 2 shows a copy of typical normal-run magnetograms. These magnetograms are recorded at stations more than 100 all over the world. These records are microfilmed and collected at the World Data Centers since the IGY (1957-58). Many magnetic observatories have older data before the IGY and some of them are also available at the WDCs.

The format of the normal-run magnetograms varies by the observatory or the sponsoring agency of the station. Main features of the normal-run magnetograms are as follows: 1) They are usually recorded on a photographic paper or chart at a speed of 20 mm/hour. 2) One day (24 hours) data is recorded on one frame. The record is replaced manually by the operator of the station every day. 3) The magnetic 3 components (either H,D,Z or X,Y, Z) are recorded on one frame. 4) Time marks are recorded at every UT (or sometimes LT) hour. There are two ways to record the time marks; one is to record a straight time-line on the record, and the other is to make the data unrecorded for about one minute. Time marks are also used to show one axis of the record and the time marks are usually recorded from edge to edge of the frame. 5) Every record has at least two base lines to show the constant data values. These base lines are also used to show another axis of the record. The scale value (sensitivity) is determined by each station and each component, and is calibrated at least once a month. 6) The treatment of scale-out data also varies by the station. Some stations use La-Cour type mechanism which allow the scale-out data be recorded as shifted data so that the scale-out data are seen on the same paper. Some stations record another magnetograms (insensitive or storm magnetogram) together with the ordinary magnetograms.

The quality of the record differs greatly by the stations. And, overlapping of the components, scale-out of the data, missing data or thin traces are inevitable for almost all stations. Especially, the records from the auroral-zone stations have more trouble of these kinds, because of very large disturbances and very severe natural environments.

From our experience we know that each station has 1 to 5 % non-readable periods including no-record period or trouble of microfilm, and we usually recover the data by shifting the scale-out data, or by using insensitive recording, or rewriting complicated crossing data with the help of comments written on the sheet.

3. Design of our digitizing system

As mentioned above, every station has some kinds of trouble and many of them are correctable or recoverable manually, so we selected a semi-automatic reading for this system to allow manual selection of data availability and to allow manual correction of data as handy as possible. We can use a full automatic reader for some high quality data, but the quality of magnetograms from AE stations is not so good to use such a convenient reader. And even if we apply a full automatic reader, we need much time to check the quality of the data and to correct errors. Recently, some observatories are taking digital data directly and can supply 1 minute data on magnetic tape. Although old AE indices are derived for hourly or 2.5 minute values, 1 minute values are more convenient to compare with data observed by satellites. It is usually very hard to digitize exact 1 minute values from normal-run magnetograms, but we developed a system to obtain 1 minute values from the normal-run magnograms.

The most common digitizing system make use of what is called "tablet" digitizing sensors. In our case, however, most of the input analogue data are available on microfilm. If we make prints from the microfilm, the cost of photographic printing may be too large, and the quality of the print will become more worse than that of microfilm (see Fig. 2). For this reason we preferred a sonic digitizing sensor. The sonic digitizer consists of a positioning pen which emits electric spark near the top end, and two microphone arrays which receive sound pulse from the pen. The time-lags of the spark determines the position in X,Y coordinates of the pen. The digitizer of this type can be used with microfilm reader screen instead of non-transparent tablet. By using this sensor we can omit a photographic processing, though it has demerits of instability of sparks and difficulty of adjustment of sparks. To decrease these demerits, we designed a software to read as many digitized points as possible and to increase fidelity of the digitizer by averaging these data points according to the significance of the data points.

4. Details of each program (operation phase)

Fig. 3 shows the flow of data processing in this system.

(A) Curve tracing

In this phase, the operator sets microfilm to the reader and feeds necessary informations to the system using a key-board written on the

curve reader (on the screen of the microfilm reader). Then the operator points 3 basic points and starts tracing. The program has 3 modes; i.e., 1) information input, 2) basic points, and 3) curve tracing. The operator selects one of these modes and can start and stop each action at any time.

In the tracing mode the system records all the data which the operator feeds by pushing the pointing pen onto the screen. The sensor read the position of the pen every 0.001 sec to 2 sec. This sampling rate is set by the operator, and about 0.05 sec sampling rate is used in our system, because this sampling rate is enough to get reliable final result and not too fast for the CPU to miss data processing or data transfer. If this sampling rate is too low and the operator moves the pen too fast, the system loses the detailed variation on the record. If it is too high, on the other hand, the system may not be able to follow the data input. Especially, the external memory (magnetic tape or disk) must be fast enough to follow data input and must have enough capacity to record the data.

(B) Base value reading

The trace program is made to be convenient in tracing the data and in that phase the operator just gives 3 basic points. In this phase the operator gives the precise informations to determine the exact (absolute if possible) value of the 3 basic points. Usually, this phase is not necessary for every digitizing data, because the base line value and the scale factor does not change for several months. So each basic point is selected one of the crossing points of time marks and base lines.

Usually one base line value is known as H_0 , but another base line value is not known for the H component, scale value is known instead. So this program read the H value of the another base line (denoted by D_0 or Z_0 on the magnetogram).

By using the length of the ruler recorded on the magnetogram, scale value and H_0 value, the base value for another base line is determined and every point on the magnetogram can then be able to be converted to time value for the H component.

Base line values are read at least 12 times for a station month. Average value and their standard deviation is calculated and checked, and only reliable value is used as the base line value. If any change of base line value or scale value is recognized or shown as a comment on the magnetogram, base line values are read more frequently and checked.

(C) Quality check

The raw data just read by the tracing program may have some spikes caused by some instability of the digitizing sensors and may have some miss-read data. This program checks and shows these data by detecting discontinuity in the raw data. Also, this program deletes single spikes from the data (but not continuous spikes). The operator can delete wrong data using a correction program.

(D) Smoothing and normalization

The raw data and the cleaned-up data show the data as the X and Y position on the microfilm reader. This program converts the position into the value and time. To have better quality, every point is weighted by the continuity of the data and averaged to give the final one minute values.

(E) Correction program

Raw, cleaned and smoothed data can have some errors because of machine troubles or operation errors. The correction program helps operator to make necessary corrections of the data by conversation with the graphic display.

5. Performance of this system

(A) Digitization speed

It takes 3 to 5 minutes to digitize (trace) one frame of the normal-run magnetograms.

(B) Rate of occurrence of unstable reading and rejection rate of spikes

From our experience, unstable reading occurs once every 100,000 points. 98 % of these unstable reading are deleted by the quality check program. Even if these data cannot be deleted by the program, the effect of the unstable reading is very small because of low weight of the unstable data point.

(C) Resolution

The reading system has 4000 (for X) x 3000 (for Y) resolution points on the effective screen of the microfilm reader. Usually the operator can pick up points within 2 resolution points (standard deviation). This resolution is about \pm 40 sec of temporal resolution and \pm 3 nT of H component on the ordinary magnetograms from the AE stations. But, because of many troubles of the records, final data may have temporal accuracy of \pm 2 min, and accuracy of data may be improved if we can use the original magnetograms instead of the microfilm copy of them.
